

Swiss Institute of Bioinformatics

# First Steps with R in Life Sciences: Graphics

**With slides from:** Diana Marek, Geoffrey Fucile, Alex Smith, Linda Dib, Leonore Wigger, Wandrille Duchemin

### Exam – 0.5 ECTS

**Take-home exam**: data analysis tasks, available on course page.

Exam is graded as "pass" or "fail".

- Submit analysis to your teacher in one week (ask for their e-mail).
- If you pass, you will receive a **certificate of achievement** from the SIB Training Team, which you can submit to your educational institution.
- If you don't take the exam, you will receive a certificate of attendance.

# Building graphics in R

# R graphics

R is powerful for plotting graphs and figures. It provides several plotting systems:

- base (widely used, comes with basic R installation)
- ggplot2 (widely used, implements the *Grammar of Graphics* (Wilkinson, Springer (2005)))
- lattice (mainly used for specialized needs, e.g. 3D plots)

They have very different syntaxes, **cannot be mixed**, and need to be learned separately. This course introduces the **R base plotting** system.

# R base plotting system

Plots are built up step by step with multiple function calls.

#### High-level graphics functions:

- draw a new plot.
- Tailor its appearance with optional arguments.

Low-level graphics functions: add graphical elements to an existing plot, piece by piece.

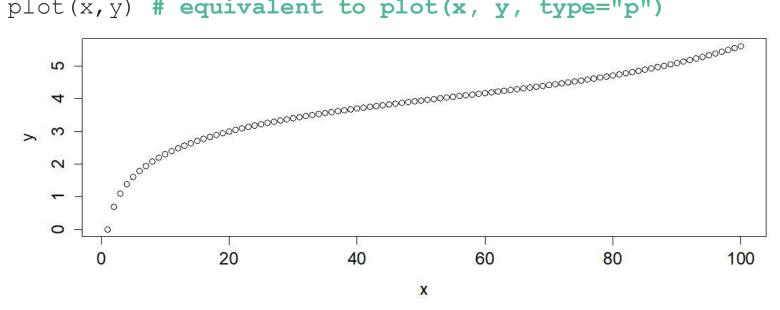

# Plotting – the basics

#### Generic function **plot()**:

- plots a variable y against a variable x.
- argument type: type of plot ("I" for lines, "p" for points, "b" for both, etc.). The default is points.

```
x <- 1:100
y <- log(x) + (x/100)^5
plot(x,y) # equivalent to plot(x, y, type="p")</pre>
```

# Adding elements to a plot

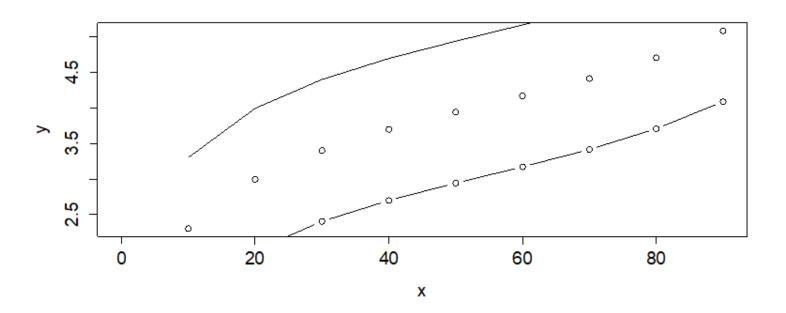

#### a new plot is created every time the plot() function is called .

low-level plotting commands: add graphical elements to an existing plot

- points() to add points to an existing plot
- lines() to add a line to an existing plot
- These function also have the **type** argument (e.g., "I" for lines, "p" for points and "b" for both).

```
x <- seq(0,100, by=10)
y <- log(x) + (x/100)^5

plot(x,y)
lines(x,y+1)
points(x,y-1, type="b")</pre>
```

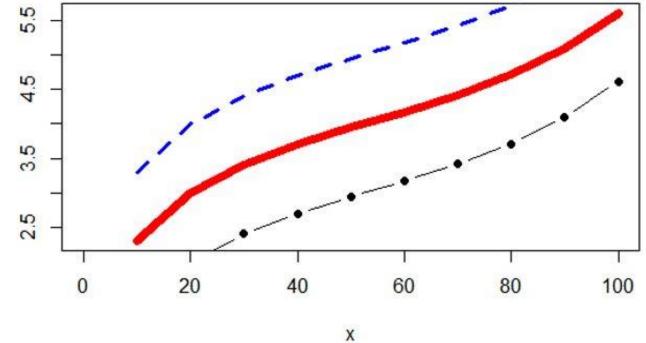

# Customizing plots (I)

plot(), points() and lines() all take customizing arguments, including:

- col indicating the colour
- **Iwd** indicating the line width
- Ity indicating the line type
- pch indicating the plotting character (symbol)

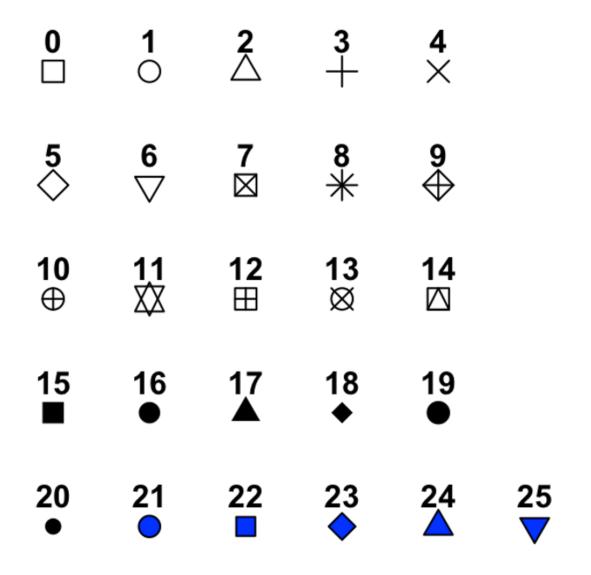

# R line types, to use with Ity

Ity=1 or 'solid' Ity=2 or 'dashed' Ity=3 or 'dotted' Ity=4 or 'dotdash' Ity=5 or 'longdash' Ity=6 or 'twodash'

### R plotting characters, to use with pch

### R color names

657 built-in color names colors () to get a full list Here is a subset -->

also possible to define colors:

- Hex codes
- RGB numbers
- Numbers 1 to 8

| white           | aliceblue       | antiquewhite    | antiquewhite1   | antiquewhite2  |

 $\underline{www.nceas.ucsb.edu/\sim} frazier/RSpatialGuides/colorPaletteCheatsheet.pdf$ 

### Customizing plots (II)

The **plot()** command takes further arguments to customize the plotting area:

- xlim and ylim to set the limits on the x- and y-axis, respectively
- **xlab** and **ylab** to set the labels for the x- and y-axis, respectively
- main to set a title

# Customizing plots (III)

#### The **legend()** command adds a legend to plots:

- x, y to set the numeric coordinates for positioning the legend.
  - OR x can be used by itself with a keyword for legend position: "bottomright", "bottom", "bottomleft", "left", "topleft", "top", "topright", "right", "center"
- **legend** to set the text to appear in the legend
- **col** to set the colours of points or lines
- Ity and Iwd to set the line types and widths for lines appearing in the legend
- pch to set the plotting symbols appearing in the legend
- bty for box type around the legend ("o" for box, "n" for no box)
- **bg** for background color

# Customizing plots (IV)

When doing a scatterplot, it is common to color the points according to a categorical variable

```
data(iris)
colormap = c( "setosa" = "red" , 'versicolor' = 'green' ,
              'virginica' = 'blue' )
plot(iris$Sepal.Length,
     iris$Sepal.Width ,
     col = colormap[ iris$Species ],
     pch=19)
```

7.5

# Digression: why does the previous trick work?

```
colormap = c( "setosa" = "red" , 'versicolor' = 'green' , 'virginica' = 'blue' )
# named vector: associate a label to some value (here a color)
colormap
   setosa versicolor virginica
     "red"
            "green" "blue"
# selecting 1 elements in a named vector,
colormap["setosa"]
setosa
"red"
# nothing prevents you from repeating an index
colormap[c("setosa", "virginica", "setosa", "setosa")]
  setosa virginica setosa
                              setosa
    "red" "blue" "red"
                              "red"
# factor are auto-coerced to numeric in this case:
c('red', 'green', 'blue') [iris$Species]
[1] "red" "green" "blue" "red" ...
```

### abline()(I)

**abline()** adds one or more straight lines through the current plot – vertical, horizontal or sloped.

#### Useful for

- showing boundaries and cutoffs
- fitting straight trend lines through the data (cf. lm())

#### Arguments:

- abline(v=c(...)): add vertical line(s) at the given x value(s)
- abline(h=c(...)): add horizontal line(s) at the given y value(s)
- abline(a=,b=): add an affine line with intercept a and slope b
- abline(reg=Im(...)): add a trend line from a linear regression equivalent to abline(Im(...))

### abline() (II) - horizontal and vertical lines

```
data(airquality) # Daily measurements, New York, May-Sept. 1973
plot(airquality$Wind, airquality$Ozone, pch=20,
        xlab= "Wind (mph)", ylab="Ozone (ppb)")
abline(h=60, col="red", lty="dashed")
abline(v=seq(3,21,3), col="grey", lty="dotdash")
                                            Air Quality, New York, May to September 1973
legend("topright",
     "Maximum allowable
                                                              Maximum allowable ozone concentration
      ozone concentration",
    col="red",
                               Ozone (ppb)
      lty="dashed")
                                  100
                                  0
                                                                    15
                                                                                20
                                                         Wind (mph)
```

### abline() (III) - trend line

#### abline(lm(airquality\$Ozone ~ airquality\$Wind), col=2, lwd=2)

```
Air Quality, New York, May to September 1973
legend("topright",
   legend= c("measures",
                                                                                           measures
                                         150
                 "fitted line"),
                                                                                           fitted line
   pch = c(20, NA),
                                      Ozone (ppb)
                                         100
   lty = c(0, 1),
   lwd=c(NA, 2),
                                         20
   col = c(1, 2),
   bg = "gray90")
                                         0
                                                                                15
                                                                                             20
                                                                   10
                                                                    Wind (mph)
```

### Let's practice - 7

Import the mouse data from the file course\_datasets/mice\_data\_mod.csv.

This file contains the same data as mice\_data.csv and in addition, two more columns.

- Run str() to check your data frame: did it load correctly?
- 2. Convert genotype and diet to factor variables.
- 3. Make a **scatter plot** of respiratory rate against mouse weights using the function plot().
  - 1. use solid circles as plotting symbol
  - 2. add a title
  - 3. customize the axis labels ("Weight [q]", "Respiratory Rate [bpm]")
  - 4. color the points by genotype.
- 4. Fit a trend line using the function abline()
- 5. Add a legend for the genotype

#### **EXTRATASKS:**

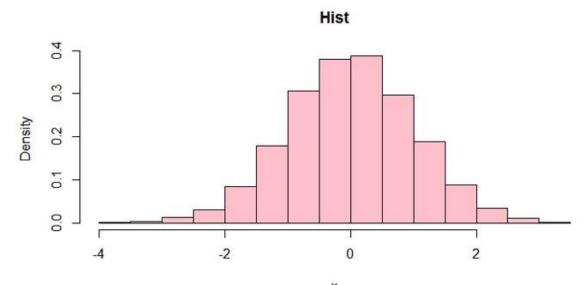

- use the command data (airquality) to load the airquality dataset
- 2. Plot the relationship between wind speed (Wind) and temperature (Temp)
  - Color by Month
  - Add nice labels and a legend

### Histograms

**hist()** creates a histogram in a new plot (like plot). Main parameters:

- breaks: guides the number of bins. Number or vector of breakpoints
- freq:
  - TRUE: y-axis represents counts per bin
  - FALSE: y-axis represents density

```
x<- rnorm(10000) # 10000 random draw in a normal distribution
```

# Histograms and density line

**density()** estimates the probability density of the data (kernel density estimates). The output of **density()** can be given to the **lines()** function.

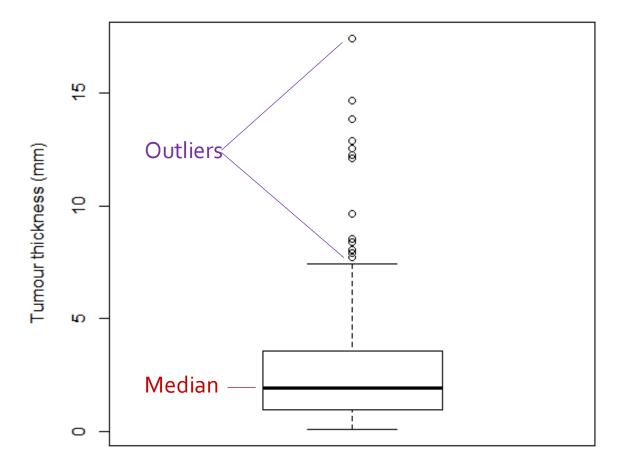

```
x<- rnorm(10000) # 10000 random draw in a normal distribution
hist(x, freq=FALSE,
         main="Hist",
                                                         Hist
         col="pink")
                                  4.0
                                  0.3
lines (density(x),
                               Density
                                  0.2
       Col="blue",
                                  0.1
       lwd=3)
                                  0.0
                                                -2
                                                           0
```

Х

# Boxplots (I) - anatomy

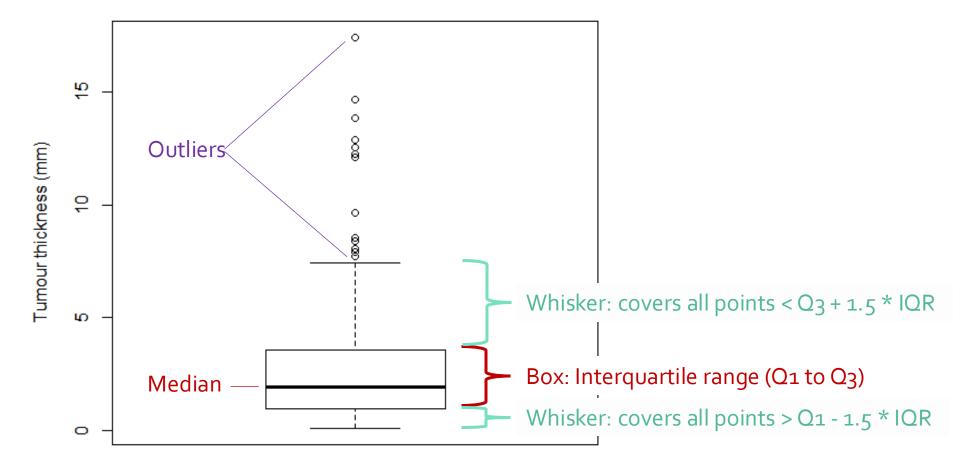

Example: melanoma thickness in 205 patients

# Boxplots (II) - anatomy

Example: melanoma thickness in 205 patients

# Boxplot (III) - plotting code

```
library (MASS)
data (Melanoma) # 205 patients with malignant melanoma
head (Melanoma)
 time status sex age year thickness ulcer
    10
            3
                   76 1972
                                6.76
   30
                   56 1968
                                0.65
   35
              1 41 1977
                               1.34
                                           Tumour thickness (mm)
   99
                  71 1968 2.90
            1 1 52 1965 12.08
   185
   204
                   28 1971
                                4.84
boxplot (Melanoma$thickness,
         ylab='Tumour thickness (mm)',
         col='white')
```

# Boxplot (IV) - more boxplots

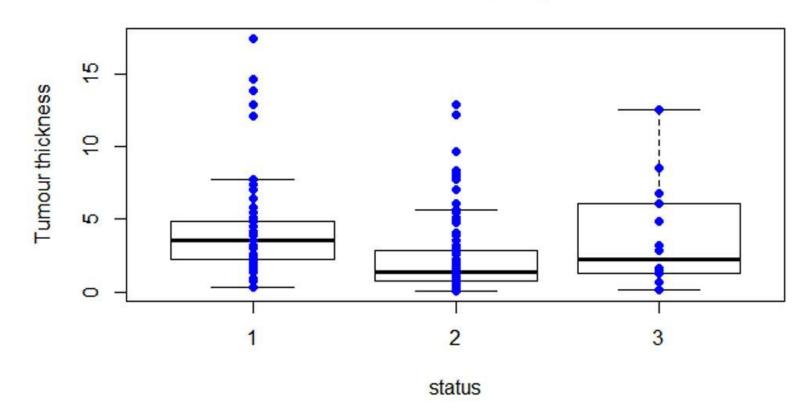

#### We want

- separate boxplots for subgroups
- 2. individual points overlaid

#### status:

- died from melanoma
- 2. alive
- 3. dead from other causes

#### Thickness of melanoma per patient status

### Boxplot (V) - data preparation

Melanoma\$status <- factor(Melanoma\$status)</pre>

```
# check if the grouping variable is a factor (it is not!)
str(Melanoma)
'data.frame': 205 obs. of 10 variables:
$ time : int 10 30 35 99 185 204 210 232 232 279 ...
$ status : int 3 3 2 3 1 1 1 3 1 1 ...
$ sex
      : int 1 1 1 0 1 1 1 0 1 0 ...
$ age : int 76 56 41 71 52 28 77 60 49 68 ...
$ year : int 1972 1968 1977 1968 1965 1971 1972 1974
$ thickness: num 6.76 0.65 1.34 2.9 12.08 ...
$ ulcer : int 1 0 0 0 1 1 1 1 1 1
# coerce the grouping variable to factor
```

# Boxplot (VI) - plotting code

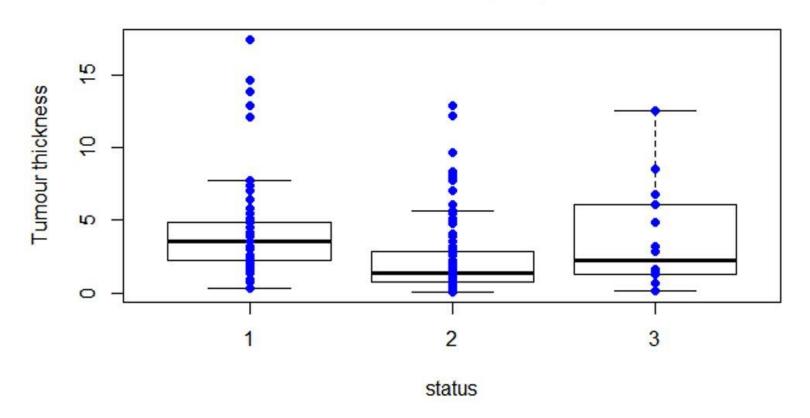

```
Method 1: data subsets
boxplot (Melanoma$thickness[Melanoma$status=="1"],
        Melanoma$thickness[Melanoma$status=="2"],
        Melanoma$thickness[Melanoma$status=="3"],
        main="Thickness of melanoma per patient status",
        xlab="status", ylab="Tumour thickness",
        names=c("1","2","3"))
points (Melanoma$status, Melanoma$thickness,
         col="blue", pch=19) #adds the actual data points to the plot
Method 2: Formulas
boxplot (thickness ~ status, data=Melanoma,
         main="Thickness of melanoma per patient status",
         xlab="status", ylab="Tumour thickness")
points (thickness ~ status, data=Melanoma,
         col="blue", pch=19) #adds the actual data points to the plot
```

# Boxplot (VII) - result

Both methods give the same result:

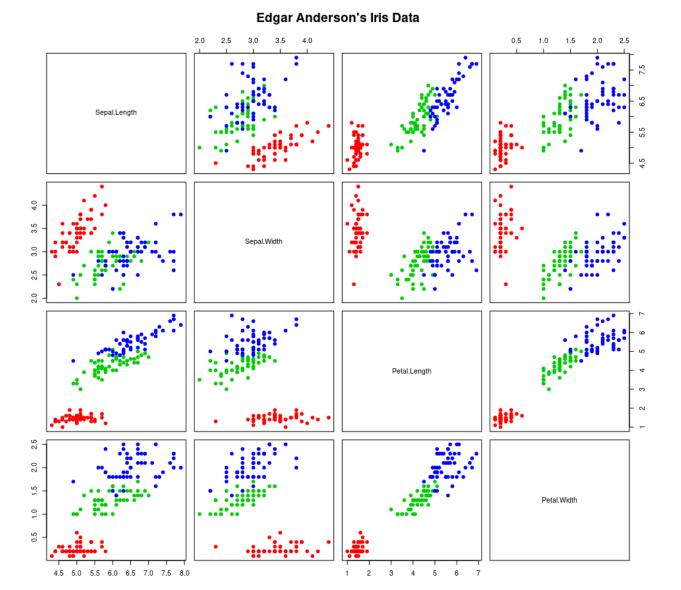

#### Thickness of melanoma per patient status

# Pairs scatter plot - pairs()

If x is a matrix or a data frame, **pairs()** draws all possible bivariate plots between the columns of x.

### Let's practice - 8

This is a continuation of the previous practice: we will continue to plot the mice data

- 1. Plot a **histogram** of mouse weight and customize it with title, labels, colors. Represent the density line on top.
- 2. Make **boxplots** of weights from WT and KO mice. Customize with title, labels, colors.
- 3. Optional: Repeat 2 with diet instead of genotype.

#### **EXTRATASKS**

Come back to the airquality dataset

- 1. Make boxplot of temperatures per month
- 2. Make boxplot of wind speed per month
- 3. for each of these plots, add labels as well as overlay the actual points onto the boxplots

# Permanent graphic changes (I)

The function **par()** allows to change the default values of many plotting parameters. All future calls to graphics functions will be affected.

**Example 1**: set plotting colors and symbols par (col="red", pch=15)

**Example 2**: set margin widths for subsequent plots

- mar sets plot margins in number of lines
- mai sets plot margins in inches
- use vectors of 4 values (c(0,1,1,2)) for the bottom, left, top, and right margins

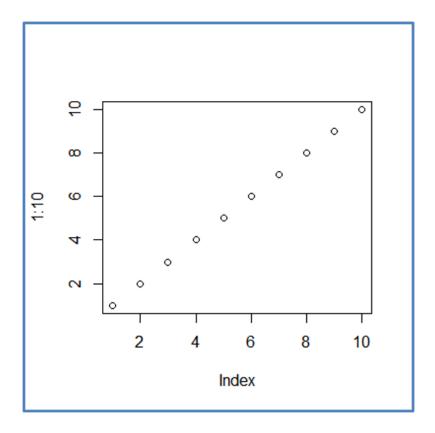

```
par(mar=c(5.1,4.1,4.1,2.1)) #set margins in lines
par(mai=c(1.02,0.82,0.82,0.42)) #set margins in inches
```

# Permanent graphic changes (II)

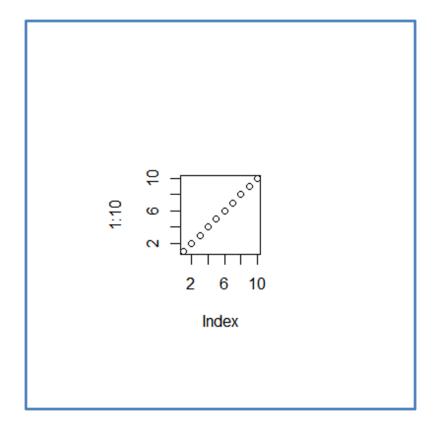

#### Normal margins

```
# bottom, left, top, right
par(mar=c(5.1, 4.1, 4.1, 2.1))
Plot(1:10)
```

#### Wide margins

```
# bottom, left, top, right
par(mar=c(8.1,8.1,8.1,8.1))
Plot(1:10)
```

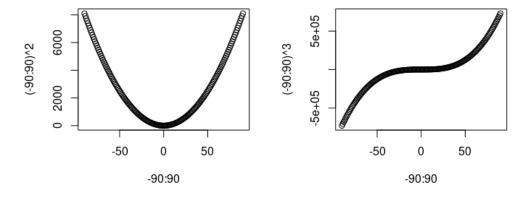

# Permanent graphic changes (III)

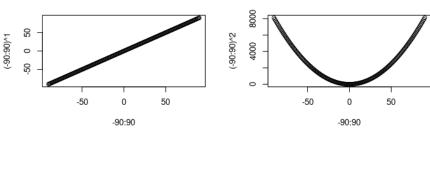

par() can be used to generate a multi-panel figures with the argument

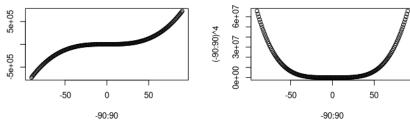

mfrow: a vector with two elements ( number of rows, number of columns)

```
par(mfrow=c(1,2))
plot(-90:90 , (-90:90)**2 )
plot(-90:90 , (-90:90)**3 )
```

```
par(mfrow=c(2,2))
plot(-90:90 , (-90:90)**1 )
plot(-90:90 , (-90:90)**2 )
plot(-90:90 , (-90:90)**3 )
plot(-90:90 , (-90:90)**4 )
```

6-90:90)^3

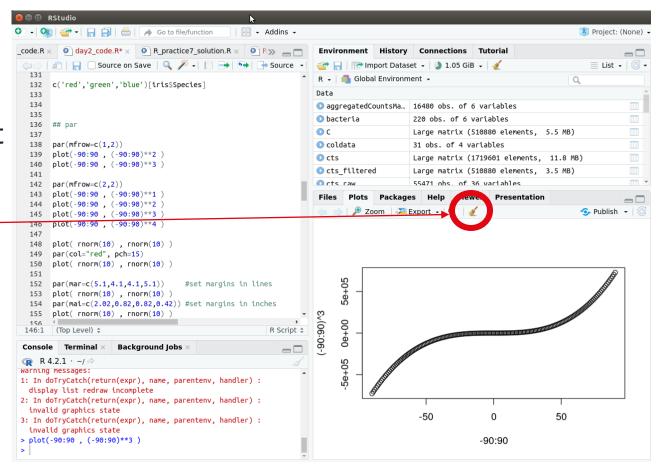

# Permanent graphic changes (IV)

Current settings of par(): call par() without arguments

#### Resetting par()

- Restart R or switch Rstudio projects
- dev.off(): closes the most recent plot
- graphics.off(): closes all plots
- Rstudio broom icon

# Saving figures to files

**Programmatic method**: surround the plotting code with

- Before format function: pdf(), png(), jpeg(),...
- After: dev.off()

```
pdf(file="quadratic_cubic.pdf", width=7, height=4, paper="a4")
plot(-90:90,(-90:90)**2)
dev.off()
```

Alternatively, you may use Rstudio interface:

- Plots > Export > Save as Image (PNG, JPEG, TIGG, BMP)
- Plots > Save as PDF

### Graphic export functions

#### Use correct file extension:

- postscript(file="a\_name.ps", ...)
  pdf(file="...pdf", ...)
  jpeg(file="...jpg", ...)
  png(file="...png", ...)
- Different devices have different set of arguments: height=, width=, res=, paper=, pointsize=, ...
- png, jpeg, tiff (raster formats): width and height are in pixels.
- pdf and postscript (vector formats): width and height in inches. Default values are 7. Tip:  $A_4 = 8.3'' \times 11.7''$ ; set the width and height a little smaller for printing to  $A_4$  size
- pdf and postscript have an argument "paper".
   paper="a4" for A4 in portrait orientation, paper="a4r" for A4 in landscape orientation

# Choosing an image file format

#### Raster graphics (png, tiff, jpeg):

- file sizes depend on the image size (number of pixels)
- once created, stretching the image leads to poor quality

#### Vector graphics (pdf, ps, eps, svg):

- file sizes depend on the number of drawing actions (e.g. number of points, lines,...)
- all elements can be scaled as desired

#### Embedding image files in MS Office documents (Word, PowerPoint):

- In Windows, png and tiff work best, pdf can get blurry. In macOS, pdf works well.
- Can also export plot from RStudio to clipboard, then paste.

#### Publication-quality figures:

Vector graphics (pdf, eps) tend to be easier to adapt as they can be resized

File size tip: when many points are plotted, pdfs can become large in file size and slow to display. When this is an issue, consider png.

### Let's practice - 9

This is a continuation of the previous practice: we will continue to plot the mice data

- Make a multi-panel figure with the four graphics (from the previous exercises) on one page
- 2. Change the code to export the figure to a **pdf** file with paper size A4. Set width and height arguments in the call to pdf() to make it look nice.
- 3. **Optional:** Export an histogram (from previous exercise) to a **png** file. Set width and height arguments in the call to png() to make it look nice.

#### **EXTRATASKS**

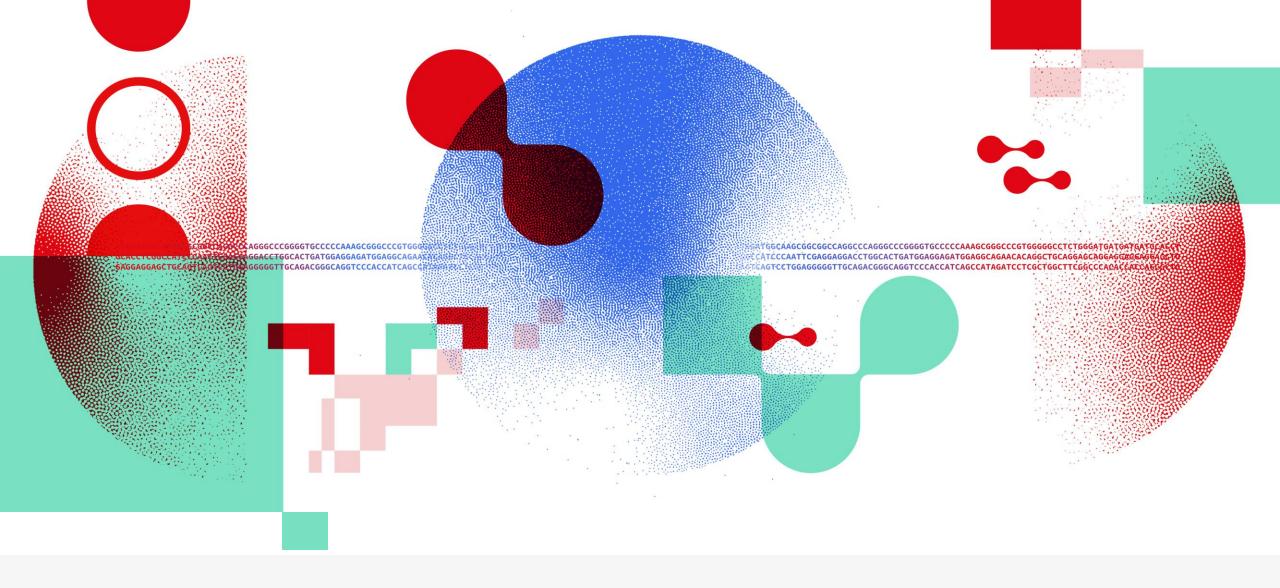

Choose 1 and try to tweak the different elements color. For example, try to change the background color, the color of the title, the thickness and color of axis labels, ...

Plots are initiated with: plot(), hist(), boxplot(), ...

Further modification with: points(), lines(), abline(), ...
